Cover: On the cover, Synchrotron Protein Footprinting--the study of protein structure and dynamics in solution using synchrotron x-ray generated hydroxyl radicals. The x-ray beam is shown in *blue* exciting water molecules and forming hydroxyl radicals. The radicals diffuse through the solution and react with surface accessible side chains of the adenovirus protease seen in space filling mode on the *left*. Protease digestion followed by chromatography and mass spectrometry is used to identify the extent and sites of oxidation. DNA binding to the protease protects specific residues from attack. Using this data, a model of DNA (*red*) binding to the protease is developed that provides a molecular mechanism for DNA-dependent activation. Caspase-activated DNase, also known as DNA fragmentation Factor 40, is responsible for this process. In this issue, Woo et al. report the crystal structure of the enzyme (pp. 531-539), which reveals a deep active site crevice that appears ideal for distinguishing internucleosomal DNA from nucleosomal DNA.
